

Hadoop MapReduce

INF 55x

Wensheng Wu

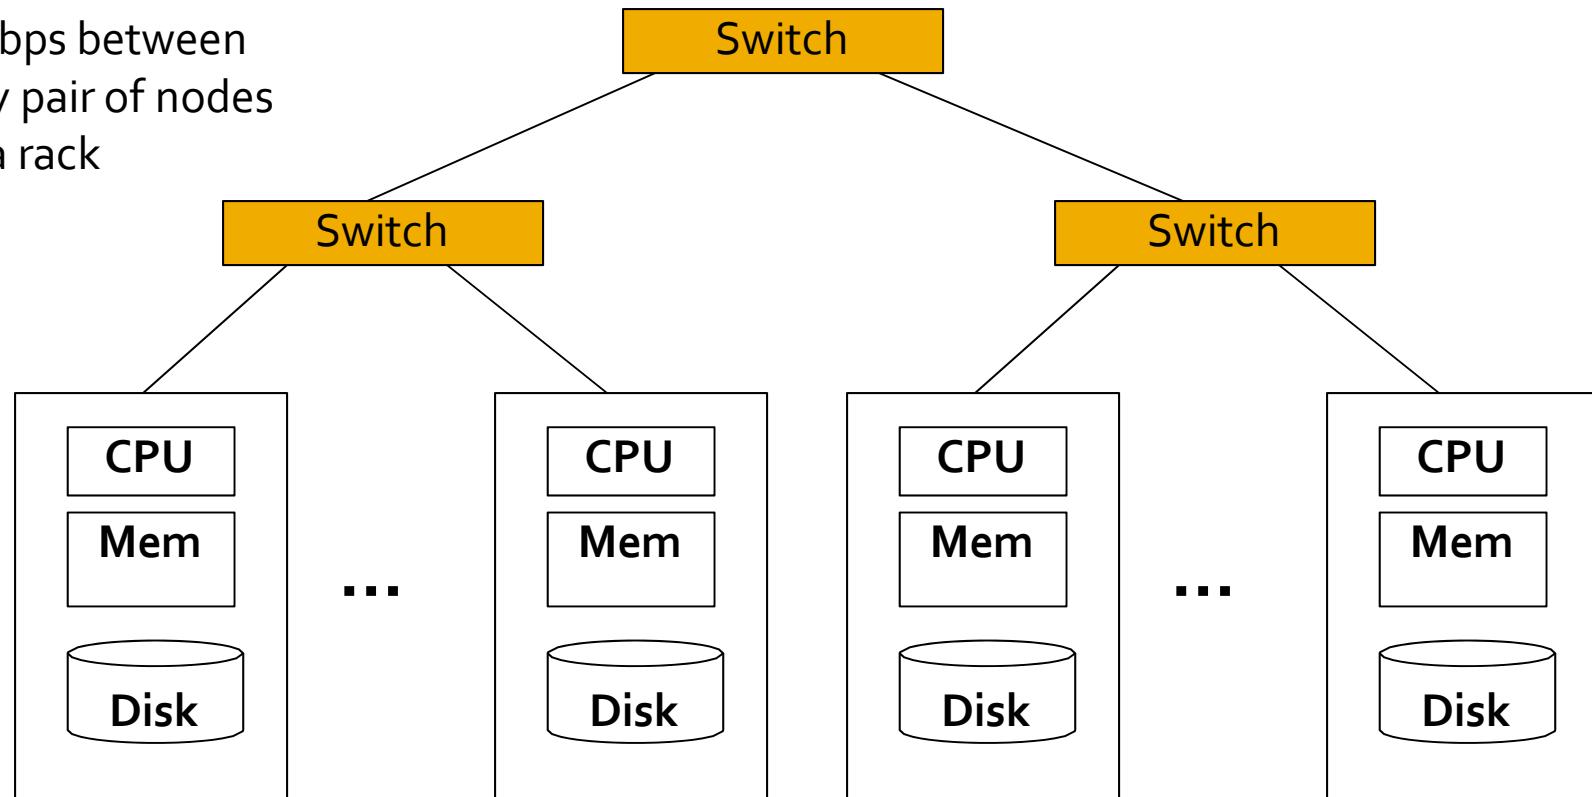

Hadoop

- A large-scale distributed batch-processing infrastructure
- Large-scale:
 - Handle a large amount of data and computation
- Distributed:
 - Distribute data & work across a number of machines
- Batch processing
 - Process a series of jobs without human intervention

Cluster Architecture

2-10 Gbps backbone between racks

1 Gbps between
any pair of nodes
in a rack

Each rack contains 16-64 nodes

In 2011 it was guestimated that Google had 1M machines, <http://bit.ly/Shh0RO>³

Roadmap

- Hadoop architecture 
 - HDFS
 - MapReduce
- MapReduce implementation
- Compile & run MapReduce programs

Key components

- HDFS (Hadoop distributed file system)
 - Distributed data storage with **high reliability**
- MapReduce
 - A parallel, distributed computational paradigm
 - With a **simplified** programming model

HDFS

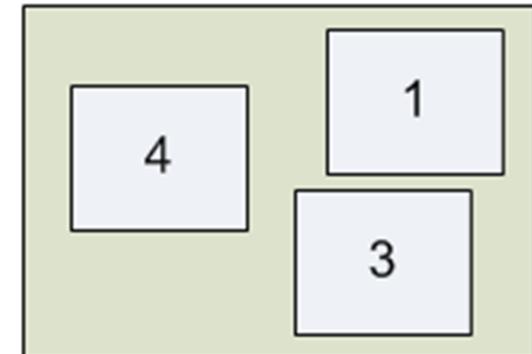

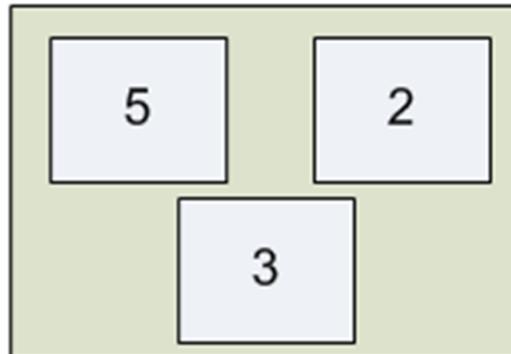

- Data are distributed among multiple data nodes
 - Data nodes may be added on demand for more storage space
- Data are replicated to cope with node failure
 - Typically replication factor = 2/3
- Requests can go to any replica
 - Removing the bottleneck (in single file server)

HDFS architecture

NameNode:
Stores metadata only

METADATA:
`/user/aaron/foo → 1, 2, 4`
`/user/aaron/bar → 3, 5`

DataNodes: Store blocks from files

HDFS has ...

- A single NameNode, storing meta data:
 - A hierarchy of directories and files
 - Attributes of directories and files
 - Mapping of files to blocks on data nodes
- A number of DataNodes:
 - Storing contents/blocks of files

Compute nodes

- Data nodes are compute nodes too
- Advantage:
 - Allow schedule computation close to data

HDFS also has ...

- A SecondaryNameNode
 - Maintaining checkpoints of NameNode
 - For recovery
- In a single-machine setup
 - all nodes correspond to the same machine

Metadata in NameNode

- NameNode has an inode for each file and dir
- Record attributes of file/dir such as
 - Permission
 - Access time
 - Modification time
- Also record mapping of files to blocks

Mapping information in NameNode

- E.g., file /user/aaron/foo consists of blocks 1, 2, and 4
- Block 1 is stored on data nodes 1 and 3
- Block 2 is stored on data nodes 1 and 2
- ...

Block size

- HDFS: 128MB
 - Much larger than disk block size (4KB)
- Why larger size in HDFS?
 - Reduce metadata required per file
 - Fast streaming read of data (since larger amount of data are sequentially laid out on disk)
 - Good for workload with largely sequential read of large file

Roadmap

- Hadoop architecture
 - HDFS
 - MapReduce 
- MapReduce implementation
- Compile & run MapReduce programs

MapReduce job

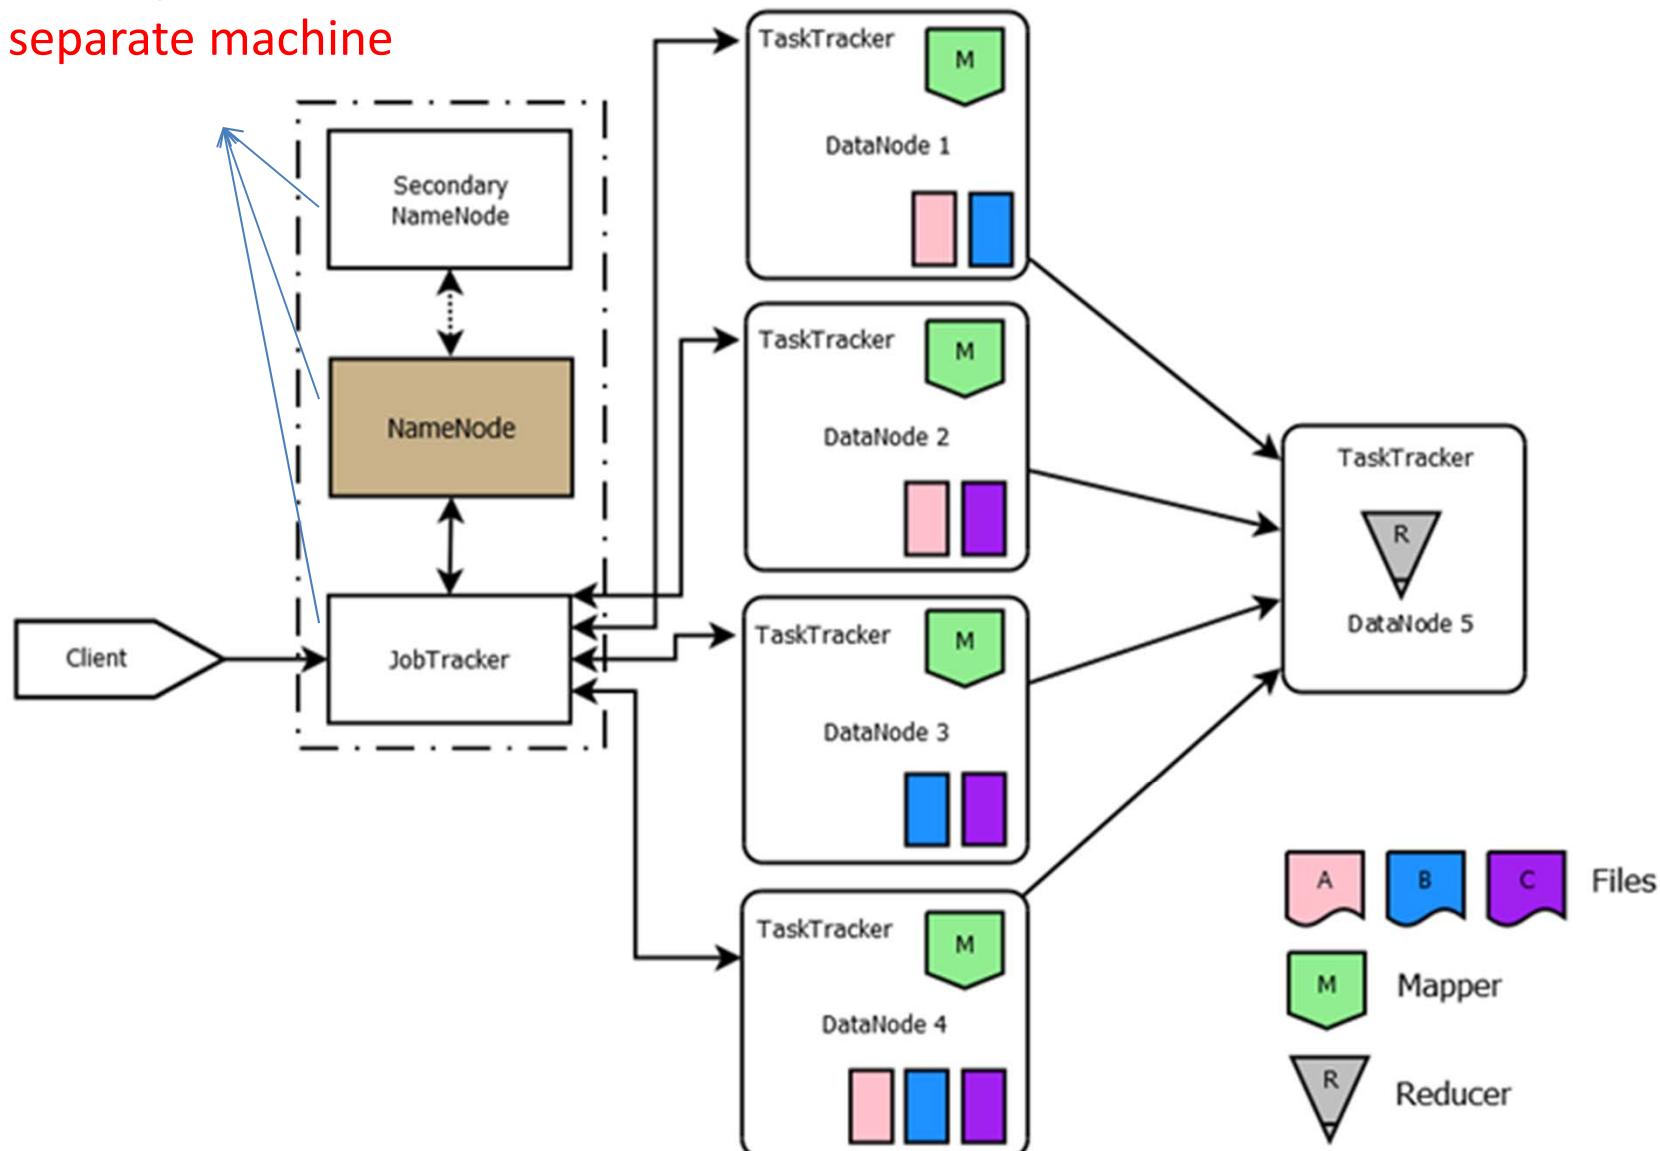

- A MapReduce job consists of a number of
 - Map tasks
 - Reduce tasks
 - (Internally) shuffle tasks

Map, reduce, and shuffle tasks

- Map task performs data transformation
- Reduce task combines results of map tasks
- Shuffle task sends output of map tasks to right reduce tasks

Hadoop cluster

Each may be run on
a separate machine

Job tracker

- Takes requests from clients (MapReduce programs)
- Ask name node for location of data
- Assign tasks to task trackers near the data
- Reassign tasks if failed

Task tracker

- Accept (map, reduce, shuffle) tasks from job trackers
- Send heart beats to job trackers: I am alive
- Monitor status of tasks and notify job tracker

Roadmap

- Hadoop architecture
 - HDFS
 - MapReduce
- MapReduce implementation
 - **Map & reduce functions and tasks**
 - Shuffling & merging
 - Input and output format
 - Combiner
- Compile & run MapReduce programs

Roots in functional programming

- Functional programming languages:
 - Python, Lisp (list processor), Scheme, Erlang, Haskell
- Two functions:
 - Map: mapping a list => list
 - Reduce: reducing a list => value
- map() and reduce() in Python
 - <https://docs.python.org/2/library/functions.html#map>

map() and reduce() in Python

- `list = [1, 2, 3]`
- `def sqr(x): return x ** 2`
- `list1 = map(sqr, list)`

What are the value of list1 and z?

- `def add(x, y): return x + y`
- `z = reduce(add, list)`

Lambda function

- Anonymous function (not bound to a name)
- `list = [1, 2, 3]`
- `list1 = map(lambda x: x ** 2, list)`
- `z = reduce(lambda x, y: x + y, list)`

How is reduce() in Python evaluated?

- $z = \text{reduce}(f, \text{list})$ where f is add function
- Initially, z (an accumulator) is set to $\text{list}[0]$
- Next, repeat $z = \text{add}(z, \text{list}[i])$ for each $i > 0$
- Return final z
- Example: $z = \text{reduce}(\text{add}, [1, 2, 3])$
 - $i = 0, z = 1; i = 1, z = 3; i = 2, z = 6$

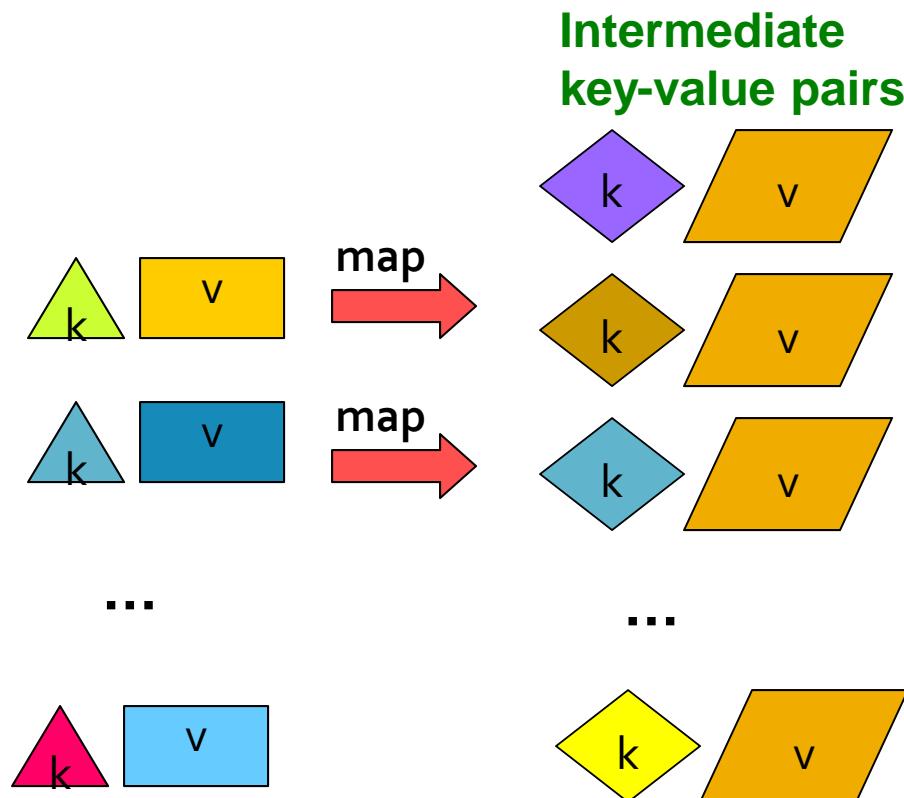

MapReduce

- Map function:
 - Input: $\langle k, v \rangle$ pair
 - Output: a list of $\langle k', v' \rangle$ pairs
- Reduce function:
 - Input: $\langle k', \text{list of } v's \rangle$ (note k's are output by map)
 - Output: a list of $\langle k'', v'' \rangle$ pairs

MapReduce: The Map Step

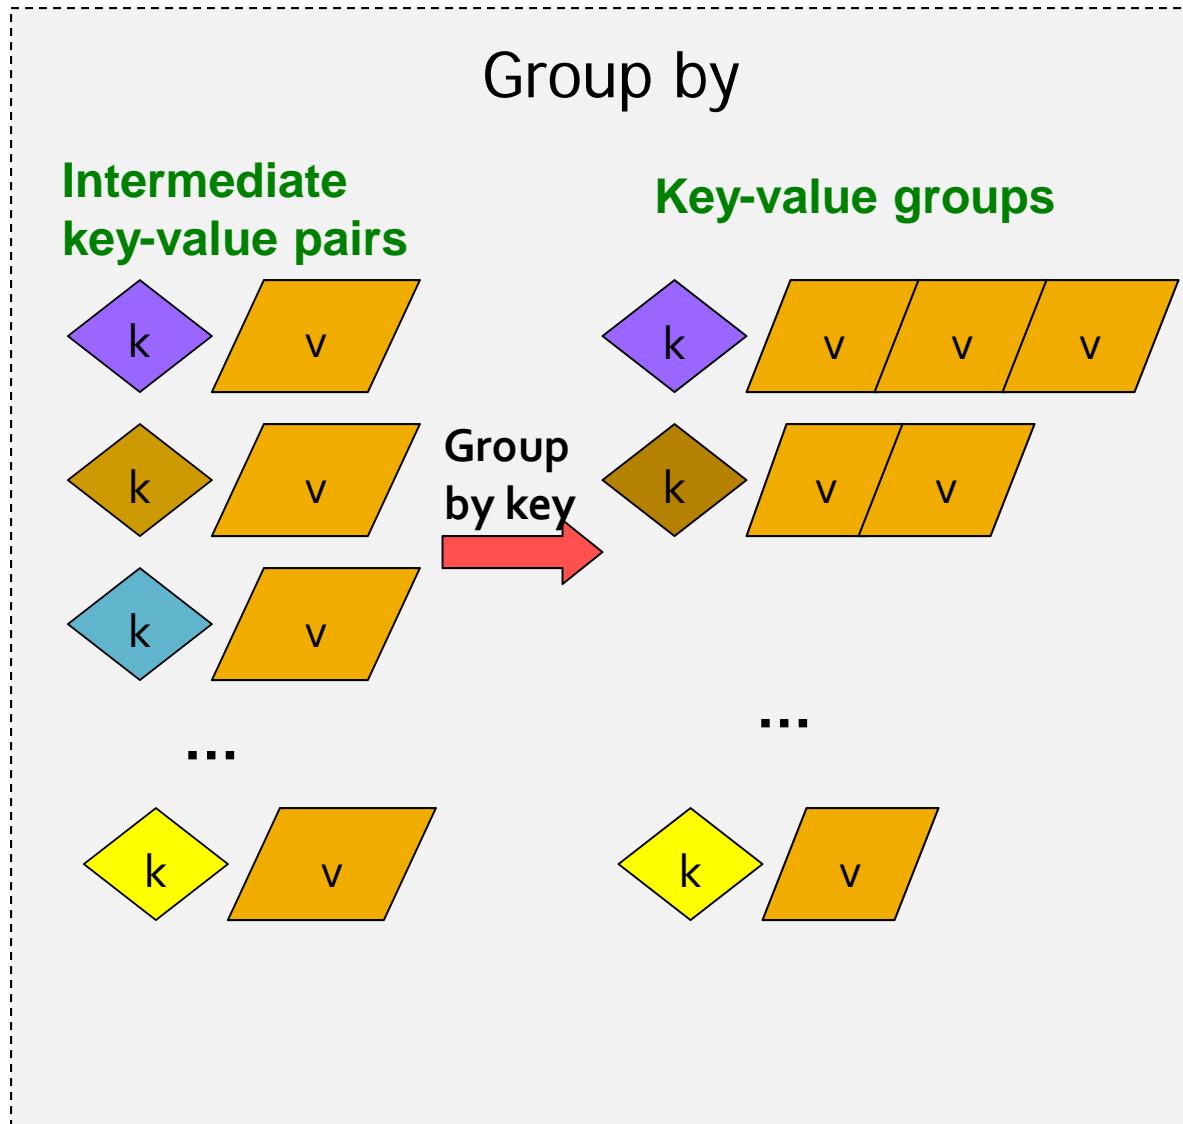

Input: key-value pairs

Output: (intermediate) key-value pairs

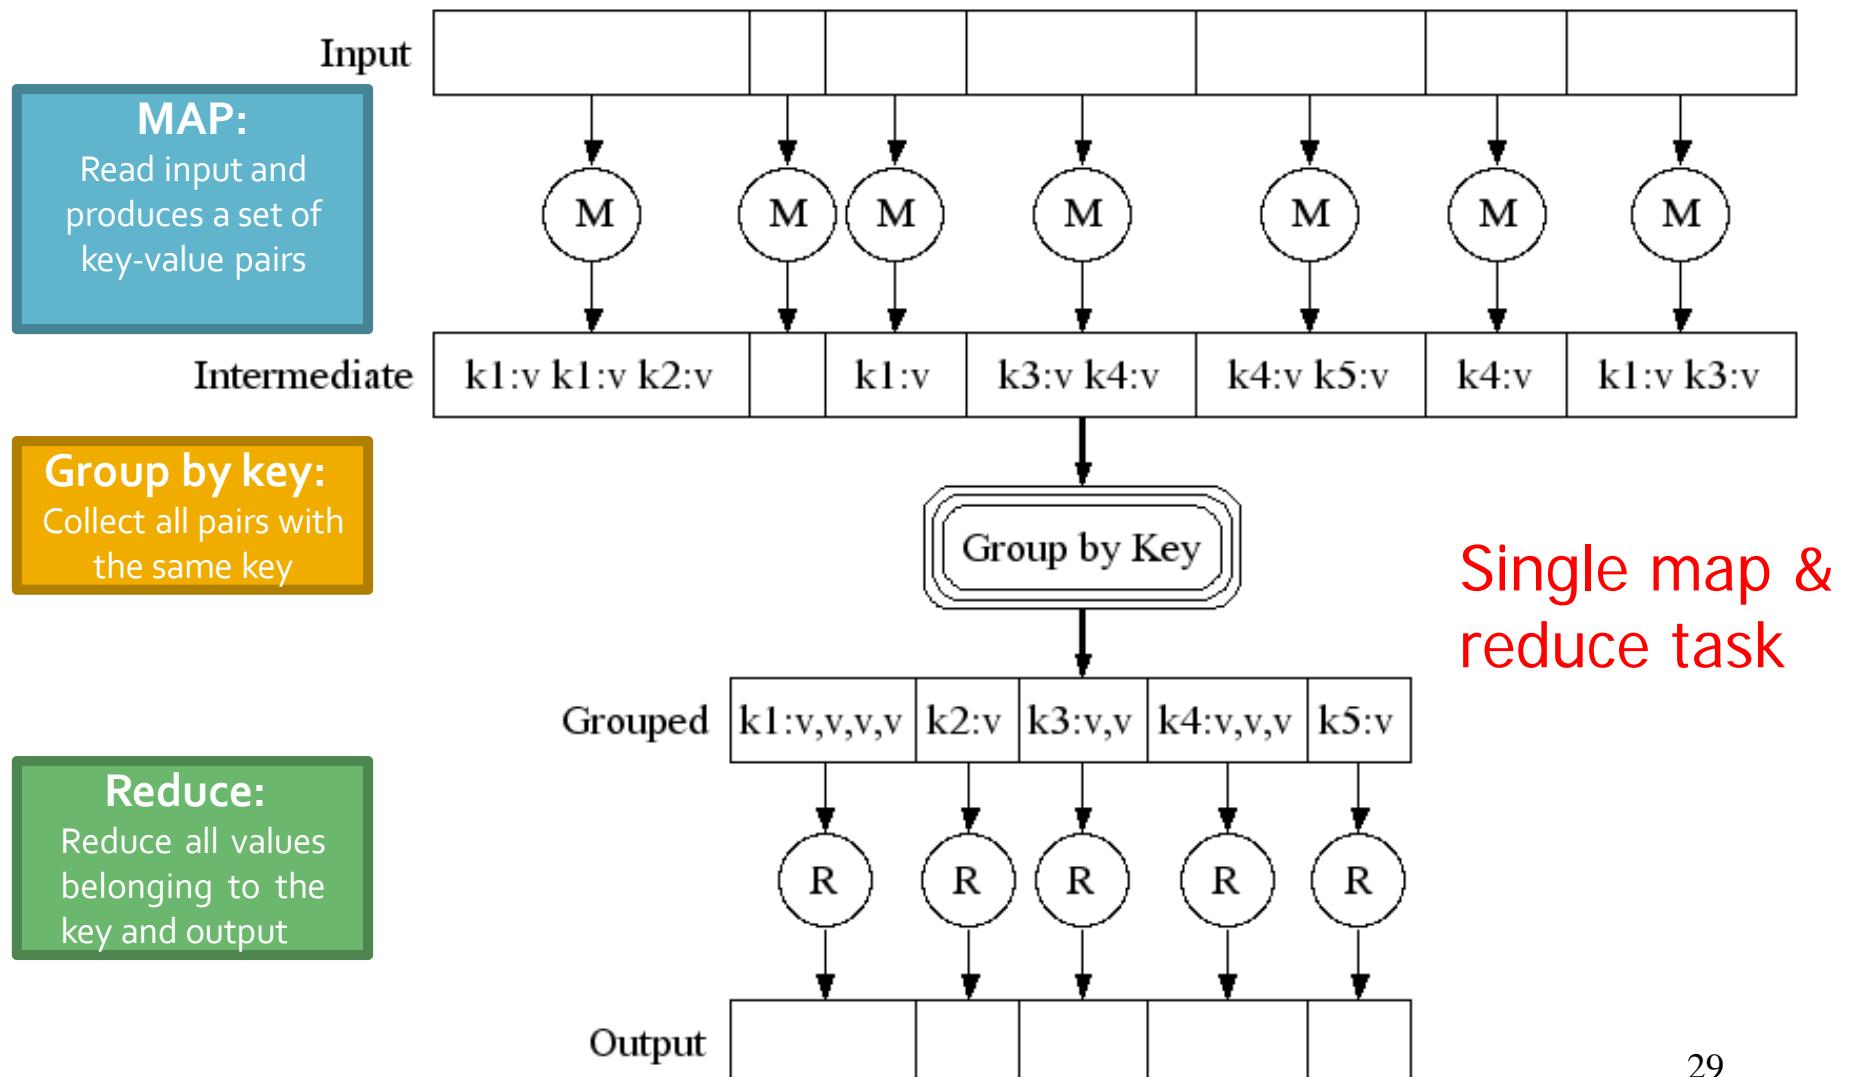

MapReduce: The Reduce Step

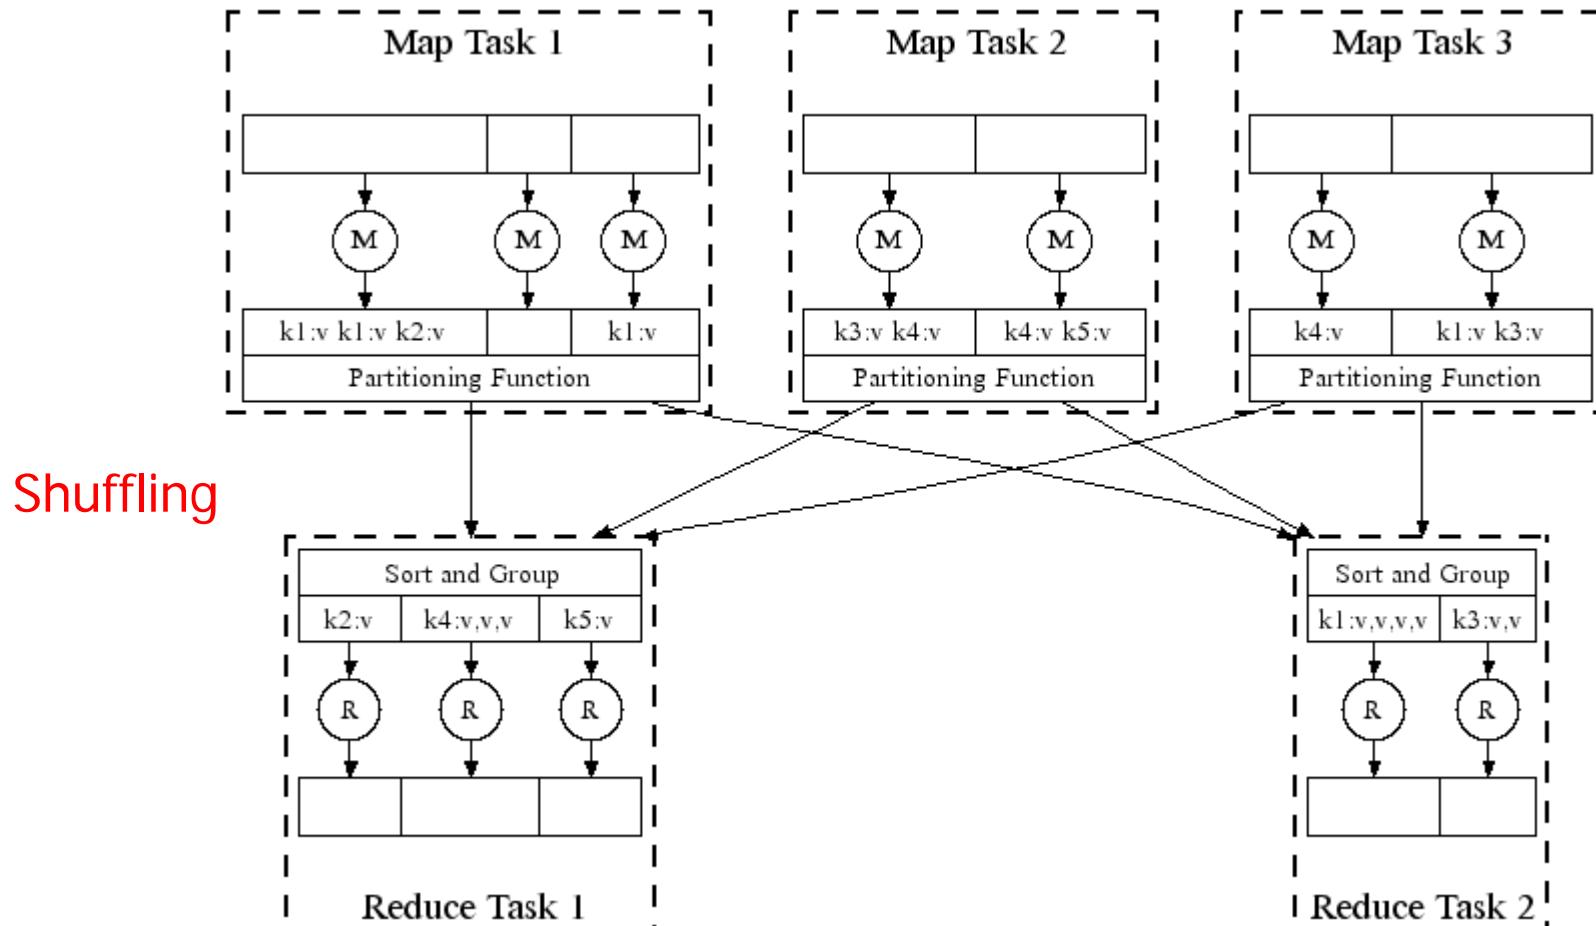

Output
key-value
pairs

Map-Reduce: A diagram

Map-Reduce: In Parallel

Multiple map & reduce tasks

Example: WordCount

- Counting the number of occurrences of words in a collection of documents
- helloworld.txt (stored under an input directory, among possible other documents)
 - hello world
 - hello this world
 - hello hello world

Example: WordCount

- Map function:
 - Input: <offset of line, line> // line = a line of text in a document
 - Output: for each word in line, output <word, 1>
- Reduce function:
 - Input: <word, list of 1's>
 - Output: <word, count> where count is the number of 1's in the input list

Word Count Using MapReduce

Pseudocode

```
map(key, value):
    // key: line offset; value: line content
    for each word w in value:
        output (w, 1)

reduce(key, values):
    // key: a word; values: an iterator over counts
    result = 0
    for each count v in values:
        result += v
    output (key, result)
```

Group by

- System groups the intermediate key-value pairs from map tasks **by key**
- E.g., <hello, 1> <hello, 1> <hello, 1> <this, 1>
=> <hello, [1, 1, 1]>, <this, [1]>

Example: WordCount

- `hadoop jar wc.jar WordCount input output`
- Output:
 - hello 4
 - this 1
 - world 3

WordCount: Mapper

Object can be replaced with LongWritable

```
public class WordCount {  
    public static class TokenizerMapper  
        extends Mapper<Object, Text, Text, IntWritable> {  
  
        private final static IntWritable one = new IntWritable(1);  
        private Text word = new Text();  
  
        public void map(Object key, Text value, Context context  
                        ) throws IOException, InterruptedException {  
            StringTokenizer itr = new StringTokenizer(value.toString());  
            while (itr.hasMoreTokens()) {  
                word.set(itr.nextToken());  
                context.write(word, one);  
            }  
        }  
    }  
}
```

Annotations:

- Data types of input key-value: Points to the type parameters `Object` and `Text` in the `Mapper` declaration.
- Data types of output key-value: Points to the type parameters `Text` and `IntWritable` in the `Mapper` declaration.
- Key-value pairs with specified data types: Points to the line `context.write(word, one);` indicating the output pairs.

WordCount: Reducer

Data types of input key-value

Should be the same as output data types of mapper

```
public static class IntSumReducer  
    extends Reducer<Text, IntWritable, Text, IntWritable> {  
    private IntWritable result = new IntWritable();  
  
    public void reduce(Text key, Iterable<IntWritable> values,  
                      Context context  
    ) throws IOException, InterruptedException {  
        int sum = 0;  
        for (IntWritable val : values) {  
            sum += val.get();  
        }  
        result.set(sum);  
        context.write(key, result);  
    }  
}
```

Annotations:

- Annotations are shown as red boxes with arrows pointing to specific code elements.
- The type parameters `<Text, IntWritable, Text, IntWritable>` are highlighted with red boxes. An arrow points from the text "Data types of input key-value" to the first `Text`. Another arrow points from the text "Data types of output key-value" to the second `Text`.
- The variable `values` is highlighted with a red box. An arrow points from the text "A list of values" to this variable.

Checking map input

```
public void map(Object key, Text value, Context context  
                ) throws IOException, InterruptedException {  
    System.out.println("map input: key=" + key + ", value=" + value);  
  
    StringTokenizer itr = new StringTokenizer(value.toString());  
    while (itr.hasMoreTokens()) {  
        word.set(itr.nextToken());  
        context.write(word, one);  
    }  
}
```

- map input: key=0, value=hello world
- map input: key=12, value=hello this world
- map input: key=29, value=hello hello world

Checking reduce input

```
public void reduce(Text key, Iterable<IntWritable> values,
                  Context context
) throws IOException, InterruptedException {

    System.out.print("reduce input: key=" + key + ", values=");

    int sum = 0;
    for (IntWritable val : values) {
        System.out.print(val + " ");
        sum += val.get();
    }

    System.out.println();
}
```

- reduce input: key=hello, values=1 1 1 1
- reduce input: key=this, values=1
- reduce input: key=world, values=1 1 1

Map and reduce tasks in Hadoop

- A node may run multiple map/reduce tasks
- Typically, **one map task per input split** (chunk of data)
- One reduce task per partition of map output
 - E.g., partition by key range or hashing

Mapper and Reducer

- Each map task runs an instance of **Mapper**
 - Mapper has a **map function**
 - Map task invokes the map function of the Mapper once for each input key-value pair
- Each reduce task runs an instance of **Reducer**
 - Reducer has a **reduce function**
 - Reduce task invokes the reduce function of the Reducer once for every different intermediate key

Reduce function

- Input: a key and an iterator over the values for the key
- Values are NOT in any particular order
- Reduce function is called once for every different key (received by the reduce task)

Roadmap

- Hadoop architecture
 - HDFS
 - MapReduce
- MapReduce implementation
 - Map & reduce functions and tasks
 - **Shuffling task**
 - Input and output format
 - Combiner
- Compile & run MapReduce programs

Shuffling

- Process of distributing intermediate key-values to the right reduce tasks
- It is **the only communication** among map and reduce tasks
 - Individual map tasks do not exchange data directly with other map tasks
 - They are not even aware of existence of their peers

Shuffling

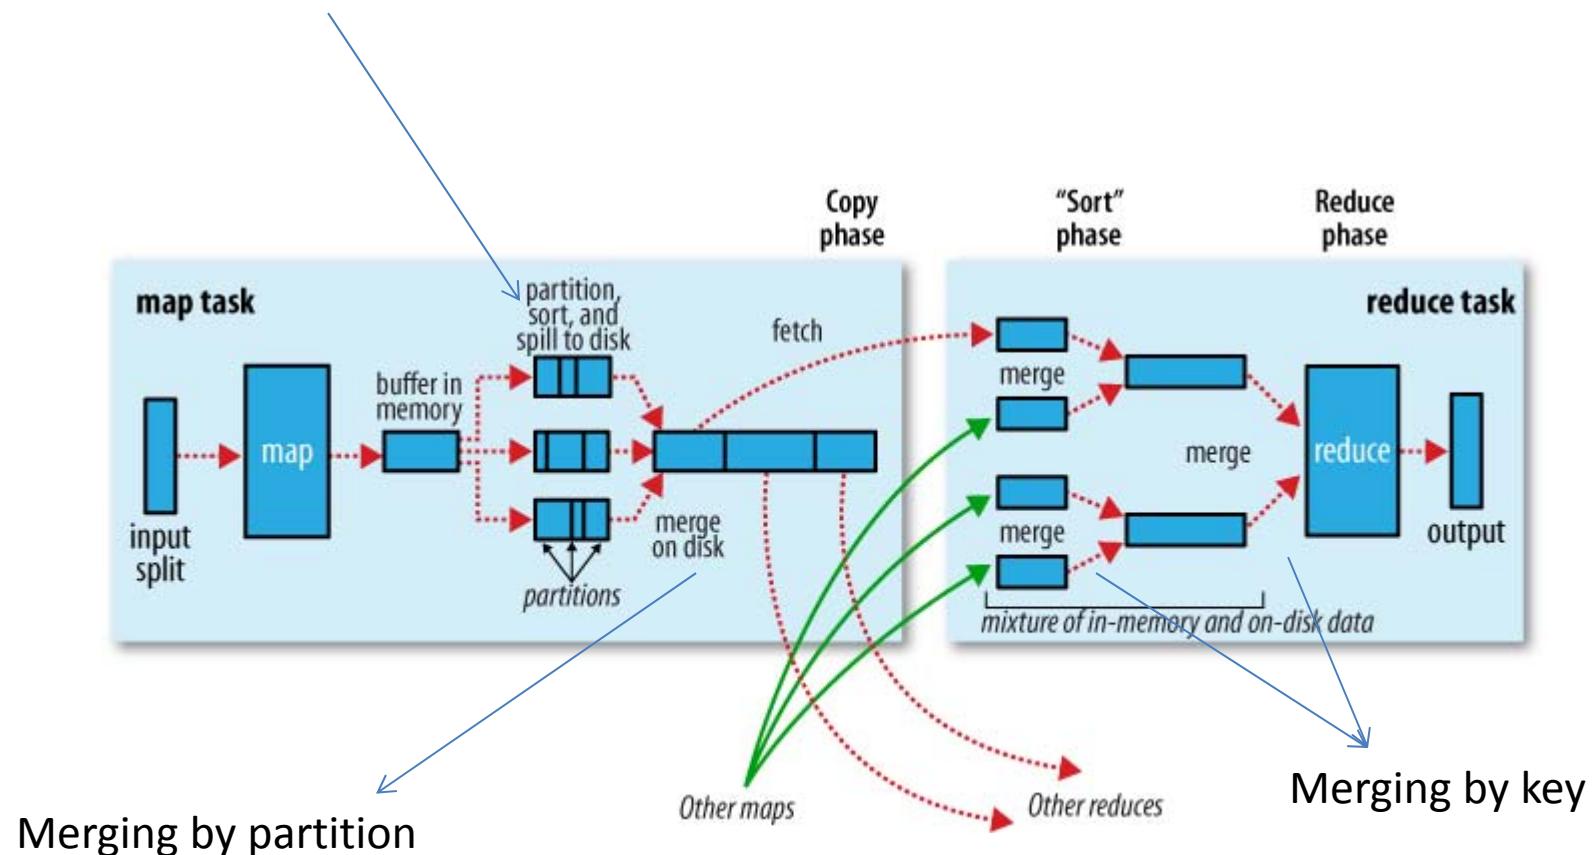

- Begins when a map task completed on a node
- All intermediate key-value pairs with the same key are sent to the same reducer task
- Partitioning method defined in Partitioner class
 - Default rule: partition by hashing the key

Internals of shuffling

- Map side
 - Partition, sort, spill & merge
- Reduce side
 - Fetch & merge

Shuffling process

Keys in the same partition are sorted (keys from different partitions may not be)

From “Hadoop: The Definitive Guide” by T. White. 47

Map side

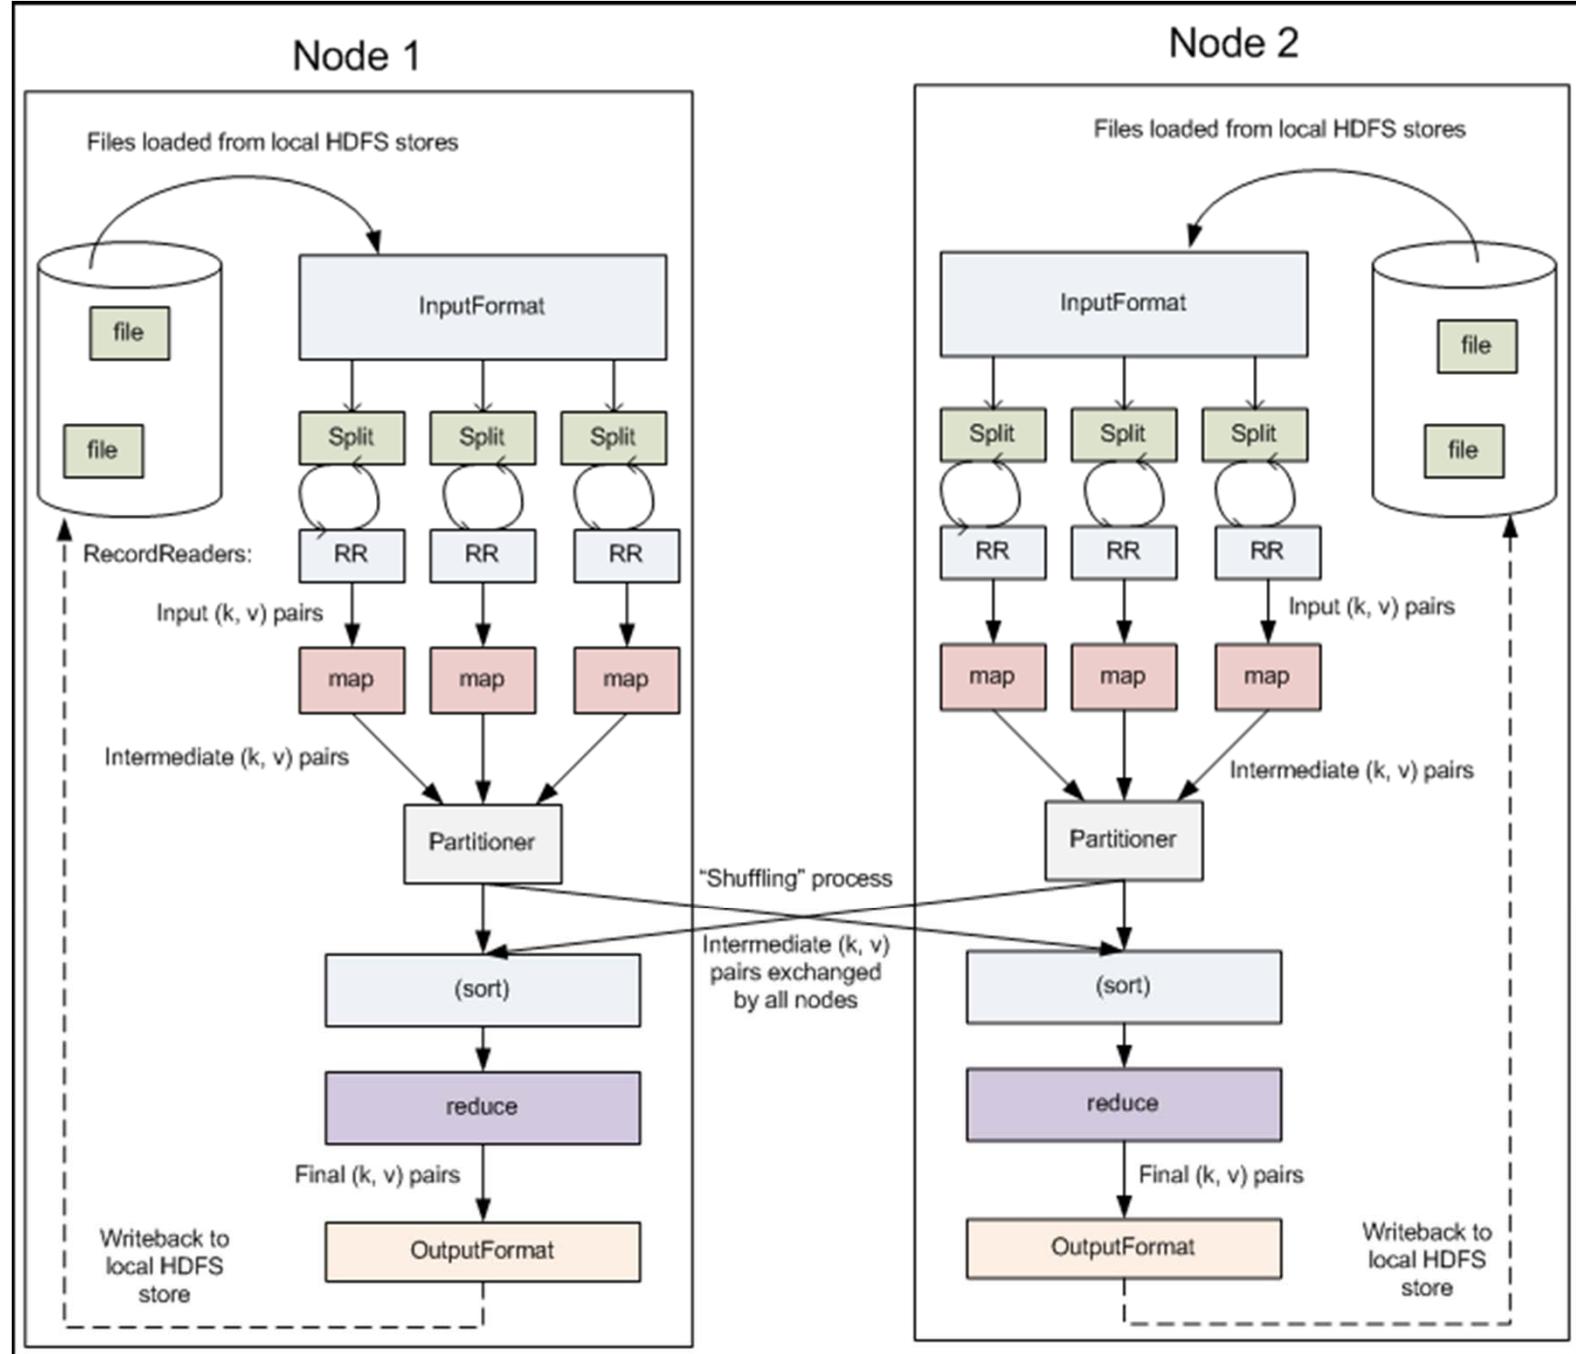

- Partition data in the buffer into R parts
 - $R = \# \text{ of reduce tasks}$
- Sort data in each partition by key
- Spill/write data in the buffer to disk
- Merge the spills
- Notify job tracker: output complete

Reduce side

- Task tracker notified by job tracker: data ready
- Fetch/copy data from map side
- Merge the data
 - Some data may sit on disk once fetched
 - This depends on the buffer size
- Figure out groups from sorted data

Roadmap

- Hadoop architecture
 - HDFS
 - MapReduce
- MapReduce implementation
 - Map & reduce functions and tasks
 - Shuffling & merging
 - **Input and output format** 
 - Combiner
- Compile & run MapReduce programs

InputFormat

- Determine how input files are split and read
- Defined in the Java interface InputFormat
- Job:
 - Split input file into chunks called InputSplits
 - Implement RecordReader to read data from splits

InputFormat implementations

- FileInputFormat (input from files in given dirs)
- DBInputFormat (input data from a database)
- CombineFileInputFormat (input data by combining multiple files)
- ...

FileInputFormat

- Job:
 - Takes paths to files
 - Read all files in the paths
 - Divide each file into one or more InputSplits
- Subclasses:
 - TextInputFormat
 - KeyValueTextInputFormat
 - SequenceFileInputFormat

Subclasses of FileInputFormat

InputFormat:	Description:	Key:	Value:
TextInputFormat	Default format; reads lines of text files	The byte offset of the line	The line content
KeyValueTextInputFormat	Parses lines into key, value pairs	Everything up to the first tab character	The remainder of the line
SequenceFileInputFormat	A Hadoop-specific high-performance binary format	user-defined	user-defined

Use non-default input format

- If input file contains tab-separated key-value pairs, e.g.,
 - John 5
 - David 6
 - ...
- `job.setInputFormatClass(KeyValueTextInputFormat.class);`
 - Both key and value are of type "Text"

InputSplits

- If a file is big, multiple splits may be created
 - Typical split size = 128MB
- A map task is created for each split
 - i.e., a chunk of some input file

RecordReader (RR)

- InputFormat defines an instance of RR
 - E.g., TextInputFormat provides LineRecordReader
- LineRecordReader
 - Form a key-value pair for every line of file
 - Data type for key: LongWritable; value: Text
- Reader is repeatedly called
 - Until all data in the split are processed

OutputFormat

- Define the format of output from Reducers
 - Output stored in a file
- Defined in the Java interface OutputFormat
- Implementation: FileOutputFormat
 - Subclasses: TextOutputFormat,
SequenceFileOutputFormat

OutputFormat

OutputFormat:

TextOutputFormat

SequenceFileOutputFormat

Description

Default; writes lines in "key \t value" form

Writes binary files suitable for reading
into subsequent MapReduce jobs

Outputs

- All Reducers write to the same directory
 - Each writes a separate file, named part-r-nnnnn
 - r: output from Reducers
 - nnnnn: partition id associated with reduce task
- Output directory
 - Set by `FileOutputFormat.setOutputPath()` method
- `OutputFormat` defines a `RecordWriter`
 - which handles the write

WordCount: setting up job

```
public static void main(String[] args) throws Exception {
    Configuration conf = new Configuration();
    String[] otherArgs = new GenericOptionsParser(conf, args).getRemainingArgs();
    if (otherArgs.length < 2) {
        System.err.println("Usage: wordcount <in> [<in>...] <out>");
        System.exit(2);
    }
    Job job = Job.getInstance(conf, "word count");
    job.setJarByClass(WordCount.class);
    job.setMapperClass(TokenizerMapper.class);
    job.setCombinerClass(IntSumReducer.class);
    job.setReducerClass(IntSumReducer.class);
    job.setOutputKeyClass(Text.class);
    job.setOutputValueClass(IntWritable.class);
    for (int i = 0; i < otherArgs.length - 1; ++i) {
        FileInputFormat.addInputPath(job, new Path(otherArgs[i]));
    }
    FileOutputFormat.setOutputPath(job,
        new Path(otherArgs[otherArgs.length - 1]));
    System.exit(job.waitForCompletion(true) ? 0 : 1);
}
```

Take multiple directories as input

Set output key and value types for both map and reduce tasks.

If Mapper has different types, use setMapOutputKeyClass and setMapOutputValueClass

setJarByClass

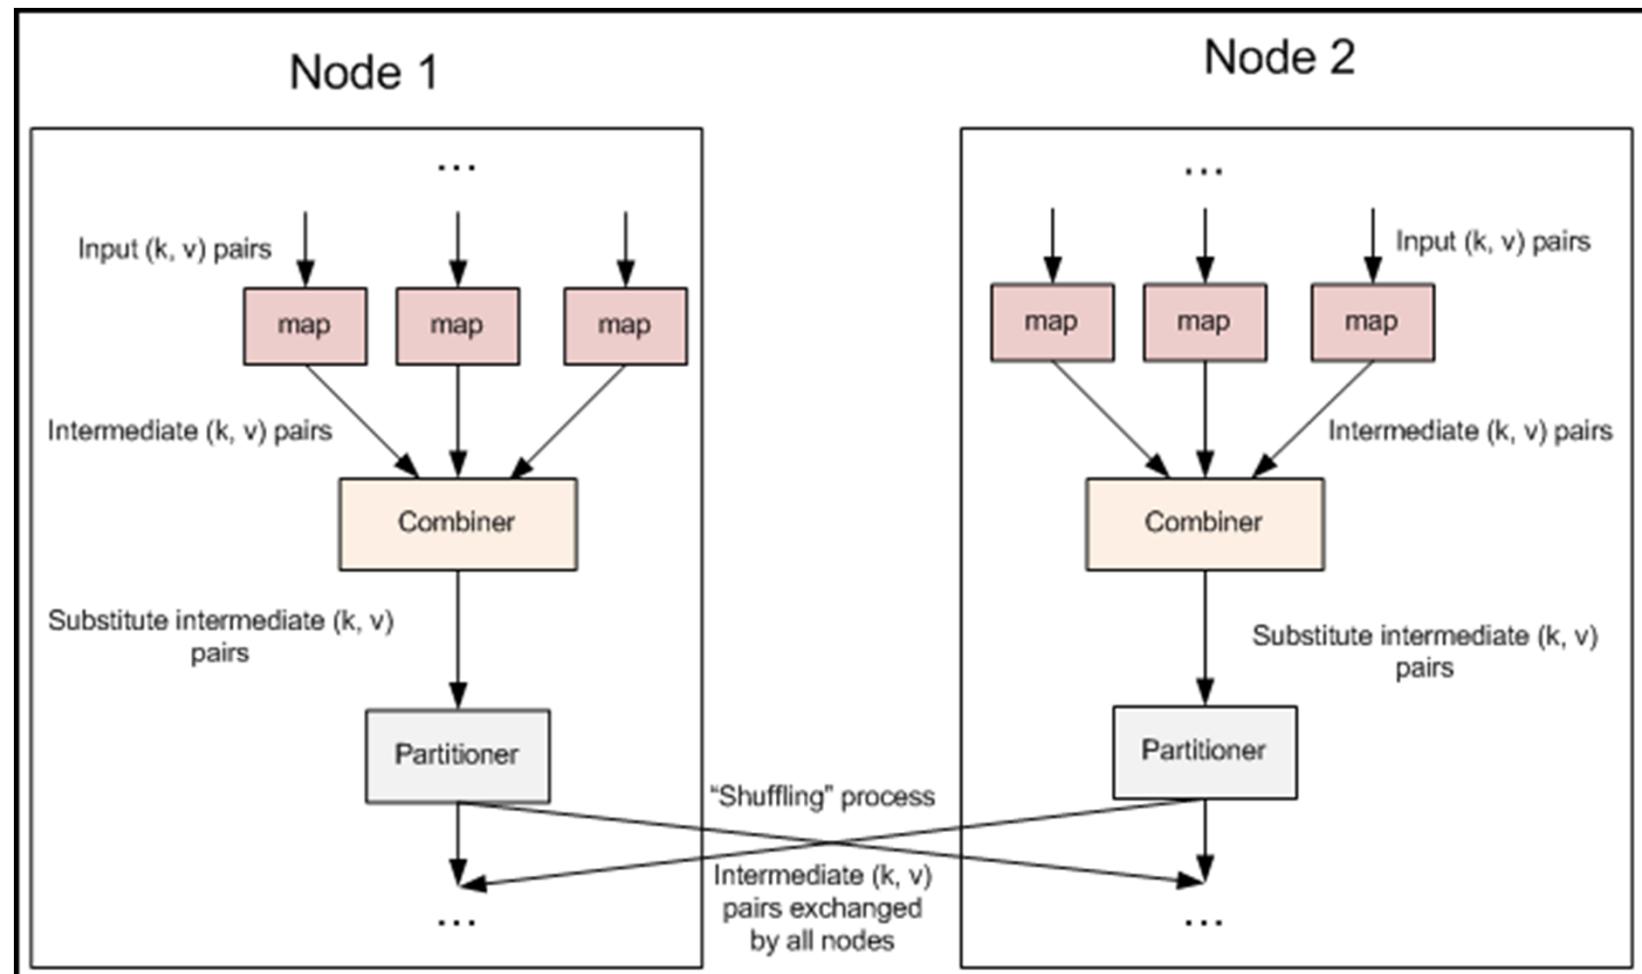

- Mapper and reducer code may be in a different jar
 - E.g., a jar in Hadoop class search path
 - (wc.jar contains only the job submission code)
- setJarByClass tells Hadoop where to find jar containing mapper and reducer code
 - By specifying its class name (e.g., WordCount)

Roadmap

- Hadoop architecture
 - HDFS
 - MapReduce
- MapReduce implementation
 - Map & reduce functions and tasks
 - Shuffling & merging
 - Input and output format
 - Combiner
- Compile & run MapReduce programs

Combiner

Combiner

- Run on the node running the Mapper
 - Perform local (or mini-) reduction
- Combine Mapper results
 - Before they are sent to the Reducers
 - Reduce communication costs
- E.g., may use a combiner in WordCount
 - (cat, 1), (cat, 1), (cat, 1) => (cat, 3)
 - One key-value pair per unique word

Without combiner

- Mapper 1 outputs:
 - (cat, 1), (cat, 1), (cat, 1), (dog, 1)
- Mapper 2 outputs:
 - (dog, 1), (dog, 1), (cat, 1)
- Suppose there is only one Reducer
 - It will receive: (cat, [1, 1, 1, 1]), (dog, [1, 1, 1])

Implementing combiner

- May directly use the reduce function
 - If it is **commutative and associative**
 - Meaning operations can be grouped & performed in any order
- Operation 'op' is commutative if:
 - $A \text{ op } B = B \text{ op } A$
- Op is associative if:
 - $A \text{ op } (B \text{ op } C) = (A \text{ op } B) \text{ op } C$

Example: without combiner

- Consider two map tasks
 - M1 => 1, 2, 3 for some key x
 - M2 => 4, 5 for the same key
- Reducer adds all values for x
 - Result = (((1 + 2) + 3) + 4) + 5

Example: with combiner

- M1 => 1, 2, 3 => combiner: $(1 + 2) + 3 \Rightarrow 6$
- M2 => 4, 5 => combiner: $4 + 5 \Rightarrow 9$
- Reducer now $6 + 9$,
 - i.e., $((1 + 2) + 3) + (4 + 5)$
 - Question: is it the same as $((1 + 2) + 3) + 4 + 5$?
- Yes, since '+' is **associative**

Example: with combiner

- M1 => 1, 2, 3 => combiner: $(1 + 2) + 3 \Rightarrow 6$
- M2 => 4, 5 => combiner: $4 + 5 \Rightarrow 9$
- Reducer may also compute **9 + 6**,
 - I.e., **$(4 + 5) + ((1 + 2) + 3)$**
 - Since values may arrive at reducer in any order
 - Question: is it the same as **$((1 + 2) + 3) + 4 + 5$** ?
- Yes, since '+' is also **commutative**

General requirements

- To use reduce function 'f' for a combiner
 - Consider a set of values S and its subsets S_1, \dots, S_k
 - It must be that: $f(S) = f(f(S_1), \dots, f(S_k))$
- E.g., in WordCount:
 - $f = \text{sum}$
 - $S = \text{a list of integers}$

Commutative and associative

- Examples
 - Sum
 - Max
 - Min
- Non-examples
 - Count
 - Average
 - Median

Custom combiner

- Key & value data type of both input & output
 - Should be same as that of the output of Mapper
 - (Also the same as that for input to Reducer)
- So if Mapper outputs (Text, IntWritable), then:
 - public static class MyCombiner
 - extends Reducer<Text, IntWritable,
Text, IntWritable> {
 - ...
 - }

Enabling combiner

- job.setCombinerClass(IntSumReducer.class)
 - To use reduce function for combiner

```
job job = Job.getInstance(conf, "word count");
job.setJarByClass(wordCount.class);
job.setMapperClass(TokenizerMapper.class);
job.setCombinerClass(IntSumReducer.class);  
↓
job.setReducerClass(IntsumReducer.class);
job.setOutputKeyClass(Text.class);
job.setOutputValueClass(Intwritable.class);
```

Roadmap

- Hadoop architecture
- MapReduce framework
- Compile & run MapReduce programs
 - On Amazon EC2

Hadoop installation

- Install the Hadoop package
 - Log into your EC2 instance and then execute:
 - wget
<http://apache.cs.utah.edu/hadoop/common/hadoop-3.1.2/hadoop-3.1.2.tar.gz>
 - tar xvf hadoop-3.1.2.tar.gz
- Might want to remove installation package (~200MB) to save space

Install java sdk

- sudo yum install java-1.8.0-devel
 - 1.8 is needed for spark

Setup environment variables

- Edit `~/.bashrc` by adding the following:
 - `export JAVA_HOME=/usr/lib/jvm/java`
 - `export HADOOP_CLASSPATH=${JAVA_HOME}/lib/tools.jar`
 - `export HADOOP_HOME=/home/ec2-user/hadoop-3.1.2`
 - `export PATH=${JAVA_HOME}/bin:${HADOOP_HOME}/bin:${PATH}`
- `source ~/.bashrc`
 - This is to get the new variables in effect
 - Or you may also log out and log in again

This assumes that you installed hadoop right under home directory

Run Hadoop in standalone mode

- Comment out <property> element (if exists) in <your hadoop installation directory>/etc/hadoop/core-site.xml as shown below

```
—> <configuration>
    <!--property>
        <name>fs.defaultFS</name>
        <value>hdfs://localhost:9000</value>
    </property-->
</configuration>
~
```

Examples

- You may find example codes here:
 - /home/ec2-user/hadoop-3.1.2/share/hadoop/mapreduce/sources/hadoop-mapreduce-examples-3.1.2-sources.jar
- unzip hadoop-mapreduce-examples-3.1.2-sources.jar
- Find WordCount.java and more under
 - org/apache/hadoop/examples/

WordCount.java

- Copy WordCount.java to a working directory of your choice
 - E.g., ~/inf551
- Comment out first line:
 - // package org.apache.hadoop.examples;

Compile & run

- Go to the directory that has WordCount.java
- hadoop com.sun.tools.javac.Main WordCount.java
- jar cf wc.jar WordCount*.class
- hadoop jar wc.jar WordCount input-hello output-hello

More examples

- Two input splits
- Multiple reducers
- SQL implemented in MapReduce
 - Selection, projection, group by, having
 - Join

Two-split example

- Now input directory has two files
 - => Two splits (hence two map tasks) generated, one for each file

```
[ec2-user@ip-172-31-52-194 inf551]$ ls input-hello2/  
helloworld1.txt helloworld2.txt  
[ec2-user@ip-172-31-52-194 inf551]$ cat input-hello2/helloworld1.txt  
hello world  
hello this world  
hello hello world  
[ec2-user@ip-172-31-52-194 inf551]$ cat input-hello2/helloworld2.txt  
hello that world  
hello this world  
hello hello that world
```

```
16/11/14 22:26:32 INFO input.FileInputFormat: Total input paths to process : 2  
16/11/14 22:26:32 INFO mapreduce.JobSubmitter: number of splits:2  
16/11/14 22:26:32 INFO mapreduce.JobSubmitter: Submitting tokens for job : job_local462978203_0001
```

Processing one split (Mapper)

- Split for "helloworld2.txt"
 - This shows map function is called 3 times
 - One for each line of text

```
16/11/14 22:26:33 INFO mapred.MapTask: Processing split: file:/home/ec2-user/hadoop-2.7.3/inf551/input-hello2/helloworld2.txt:0+57
16/11/14 22:26:33 INFO mapred.MapTask: (EQUATOR) 0 kvi 26214396(104857584)
16/11/14 22:26:33 INFO mapred.MapTask: mapreduce.task.io.sort.mb: 100
16/11/14 22:26:33 INFO mapred.MapTask: soft limit at 83886080
16/11/14 22:26:33 INFO mapred.MapTask: bufstart = 0; bufvoid = 104857600
16/11/14 22:26:33 INFO mapred.MapTask: kvstart = 26214396; length = 6553600
16/11/14 22:26:33 INFO mapred.MapTask: Map output collector class = org.apache.hadoop.mapred.MapTask$MapOutputBuffer
map input: key=0, value=hello that world
map input: key=17, value=hello this world
map input: key=34, value=hello hello that world
```

Processing one split (combiner)

- This shows input key-values for combiner
 - Note combiner uses the same reduce function

```
16/11/14 22:26:33 INFO mapred.MapTask: kvstart = 26214396(104857584); kv  
end = 26214360(104857440); length = 37/6553600  
reduce input: key=hello, values=1 1 1 1  
reduce input: key=that, values=1 1  
reduce input: key=this, values=1  
reduce input: key=world, values=1 1 1  
16/11/14 22:26:33 INFO mapred.MapTask: Finished spill 0  
16/11/14 22:26:33 INFO mapred.Task: Task:attempt_1462073202_0001_m_000000_0
```

Process the other split (Mapper)

- helloworld1.txt

```
16/11/14 22:26:33 INFO mapred.MapTask: Processing split: file:/home/ec2-user/hadoop-2.7.3/inf551/input-hello2/helloworld1.txt:0+47
16/11/14 22:26:33 INFO mapred.MapTask: (EQUATOR) 0 kvi 26214396(104857584)
16/11/14 22:26:33 INFO mapred.MapTask: mapreduce.task.io.sort.mb: 100
16/11/14 22:26:33 INFO mapred.MapTask: soft limit at 83886080
16/11/14 22:26:33 INFO mapred.MapTask: bufstart = 0; bufvoid = 104857600
16/11/14 22:26:33 INFO mapred.MapTask: kvstart = 26214396; length = 6553600
16/11/14 22:26:33 INFO mapred.MapTask: Map output collector class = org.apache.hadoop.mapred.MapTask$MapOutputBuffer
map input: key=0, value=hello world
map input: key=12, value=hello this world
map input: key=29, value=hello hello world
16/11/14 22:26:33 INFO mapred.MapTask: map() time=11ms
```

Process the other split (combiner)

- This shows the input to the combiner for the 2nd Map task

```
16/11/14 22:26:33 INFO mapred.MapTask: kvstart = 26214396(104857584); kv  
end = 26214368(104857472); length = 29/6553600  
reduce input: key=hello, values=1 1 1 1  
reduce input: key=this, values=1  
reduce input: key=world, values=1 1 1
```

Reducer input (one Reducer)

- Assume only one Reducer is used
 - Note the input values now contain local counts

```
16/11/14 22:26:33 INFO Configuration.deprecation: mapred.skip.on is depr  
ecated. Instead, use mapreduce.job.skiprecords  
reduce input: key=hello, values=4 4  
reduce input: key=that, values=2  
reduce input: key=this, values=1 1  
reduce input: key=world, values=3 3  
16/11/14 22:26:33 INFO mapred.Task: Task:attempt_local462978203_0001_r_0  
00000 0 is done. And is in the process of committing
```

Setting number of Reducers

- job.setNumReduceTasks(2);
 - Two reduce tasks

```
job job = Job.getInstance(conf, "word count");
job.setJarByClass(wordCount.class);
job.setMapperClass(TokenizerMapper.class);

job.setCombinerClass(IntSumReducer.class);

job.setReducerClass(IntSumReducer.class);
job.setOutputKeyClass(Text.class);
job.setOutputValueClass(IntWritable.class);

job.setNumReduceTasks(2);
```

Two-Reducer case

- Note "that" is in one partition
- "hello", "this", "world" in the other

```
16/11/14 22:44:31 INFO configuration.Deprecated: mapreduce.skip.on is depre-
ecated. Instead, use mapreduce.job.skiprecords
reduce input: key=that, values=2
16/11/14 22:44:31 INFO mapred.Task: Task:attempt_local1764839547_0001_r_
000000_0 is done. And is in the process of committing
16/11/14 22:44:31 INFO mapred.LocalJobRunner: 2 / 2 copied.
```

```
reduce input: key=hello, values=4 4
reduce input: key=this, values=1 1
reduce input: key=world, values=3 3
16/11/14 22:44:31 INFO mapred.Task: Tas
```

Two output files

- Part-r-00000 for partition 00000
- Part-r-00001 for partition 00001

```
[ec2-user@ip-172-31-52-194 output-hello2-r2]$ ls  
part-r-00000  part-r-00001  _SUCCESS  
[ec2-user@ip-172-31-52-194 output-hello2-r2]$ cat part-r-00000  
that      2  
[ec2-user@ip-172-31-52-194 output-hello2-r2]$ cat part-r-00001  
hello     8  
this      2  
world     6
```

More examples

- Two input splits
- Multiple reducers
- SQL implemented in MapReduce
 - Selection, projection, group by, having
 - Join

Example

- Employee.txt

100,John,25,M
200,Mary,23,F
300,David,23,M
400,Bill,26,M
500,Jennifer,20,F
600,Maria,28,F

Id, name, age, gender

```
SELECT name  
FROM Emp  
WHERE gender = 'M'
```

```
SELECT gender, count(*)  
FROM Emp  
WHERE age > 22  
GROUP BY gender
```

Join

- $R(A, B) \bowtie S(A, C)$
- Idea:
 - Use group-by in MapReduce to find joining tuples

Join

- $R(A, B) \bowtie S(A, C)$
- Map:
 - $r(a, b) \Rightarrow (a, ('R', b))$
 - $s(a, c) \Rightarrow (a, ('S', c))$
- Reduce:
 - Joining every R tuple with every S tuple with same key
 - $(a, [('R', b), ('S', c1), ('S', c2)]) \Rightarrow (a, (b, c1)), (a, (b, c2))$

Join

- Dangling tuples:
 - Key with values from only one relation
 - $(a, [('R', b)]) \Rightarrow$ left dangling
 - $(a, [('S', c)]) \Rightarrow$ right dangling

Implementation

- Each relation stored as a text file
 - In different input directories (say R and S)
 - E.g., R/tuples.txt, S/tuples.txt
- bin/hadoop jar join.jar R S output
- Need to use MultipleInputs class
 - org.apache.hadoop.mapreduce.lib.input.MultipleInputs

Implementation

- `MultipleInputs.addInputPath(job,
 new Path(args[0]),
 KeyValueTextInputFormat.class,
 RMapper.class);`

Reading tuples from R
- `tuples.txt` contains tab-separated key-value tuples
 - john 25
 - mary 36
 - ...
- `RMapper` handles:
 - `r(a, b) => (a, ('R', b))`
